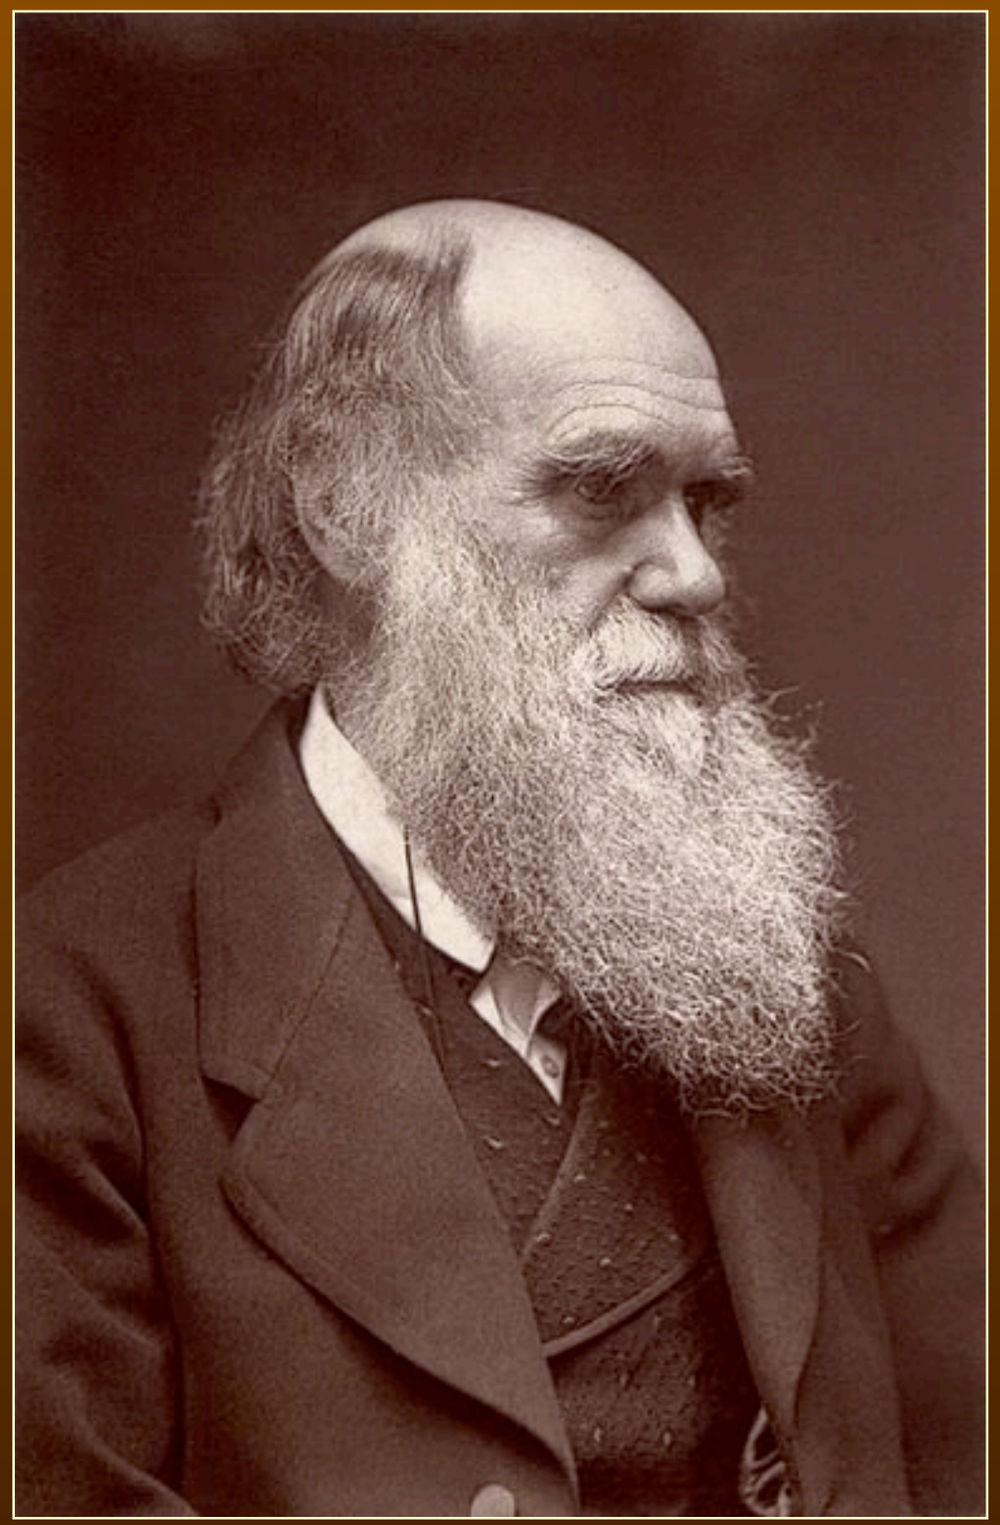
Existing knowledge of human diversity

Some fossil evidence

Darwin's revolutionary theories:



(*Source:* Robert Ashby Collection / John G. Murdoch)

- ★ All living things stem from a common ancestor. The process of speciation creates diversity by splitting existing species.
- ★ Populations adapt to their present local environment due to the differential survival and reproduction of individuals in that environment ("natural selection").
- ★ The organismal diversity we observe today is the result of a slow, deliberate process of selection and speciation.

Gregor Mendel

- ★ Inheritance is particulate. We now call these particles “genes”.
- ★ [Eukaryotic] organisms possess two copies of each gene; these copies may differ or be identical.
- ★ Individual organisms inherit one copy of each gene from each of their parents.
- ★ Our two gene copies can interact in a variety of ways to produce traits.

Y Chromosome:

[ROUTE MAPS]

TRACKING Y CHROMOSOMES THROUGH TIME

Geneticists can track the path of ancient migrations by examining genetic markers in Y chromosomes from men who hail from different parts of the world. Each marker, such as M168 or M89, identifies a lineage of men and where the lineage originated. By building an evolutionary tree based on observing many living people with the markers, investigators can determine the approximate ages of the lineages.

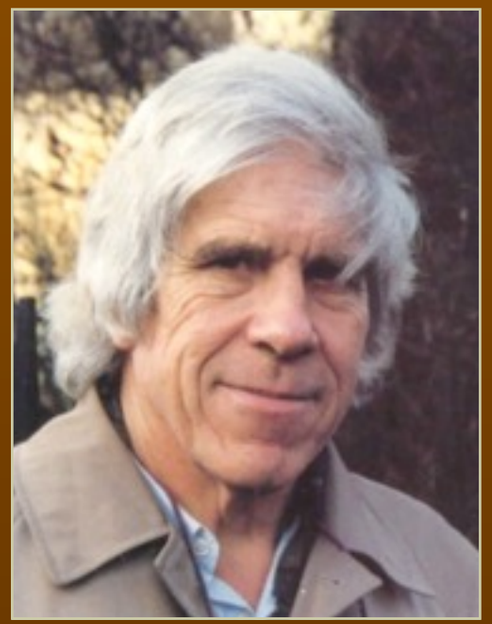
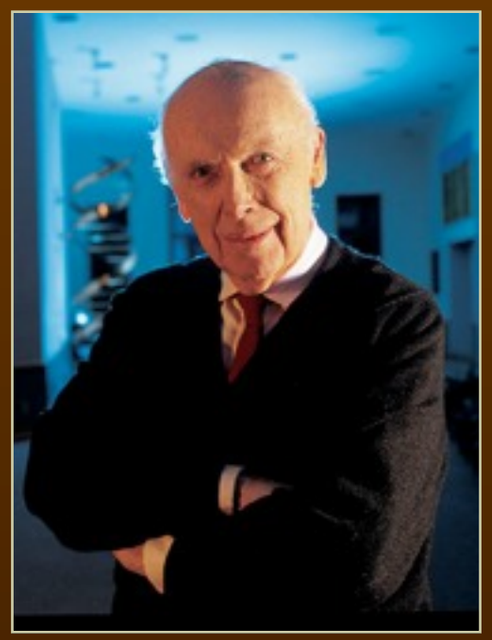
Reasons to worry about genomics?



1936-2000

Hamilton left behind him the almost completed manuscript of the second volume of his autobiography and this contained ... a foreword expressing his belief that only a radical programme of infanticide, eugenics, and euthanasia could save the human race from an imminent catastrophe. "I predict that in two generations the damage being done to the human genome by the ante and post-natal life-saving efforts of modern medicine will be obvious to all."

(*Source:* http://lclane2.net/hamilton.html)



1928-

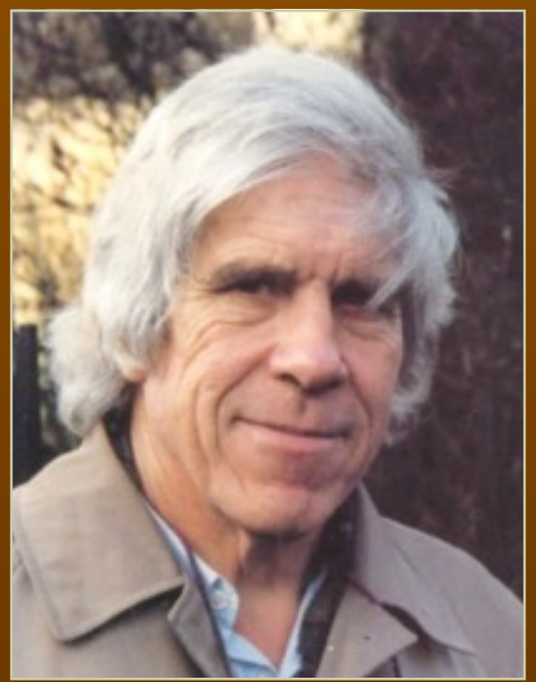
"[I am] inherently gloomy about the prospect of Africa [because] all our social policies are based on the fact that their intelligence is the same as ours—whereas all the testing says not really."

(*Source:* http://www.thedailybeast.com/newsweek/galleries/2010/04/07/smart-people-dumb-quotes.html)

Witnesses were flabbergasted when the 72-year-old discoverer of the double helix suggested there was a biochemical link between exposure to sunlight and sexual urges. “That's why you have Latin lovers,” Watson said. “You've never heard of an English lover. Only an English patient.”

(*Source:* http://www.sfgate.com/cgi-bin/article.cgi?file=/chronicle/archive/2000/11/13/MN111208.DTL)

Why do these prominent scientists espouse eugenic beliefs?

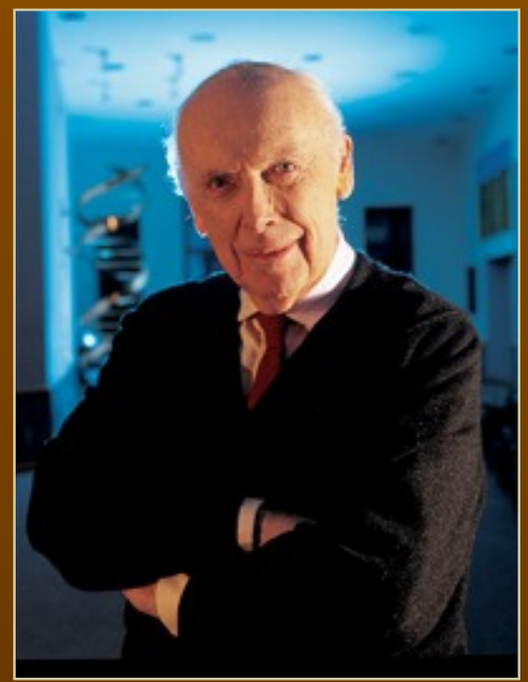


Both take a very reductionist, gene-centered approach:

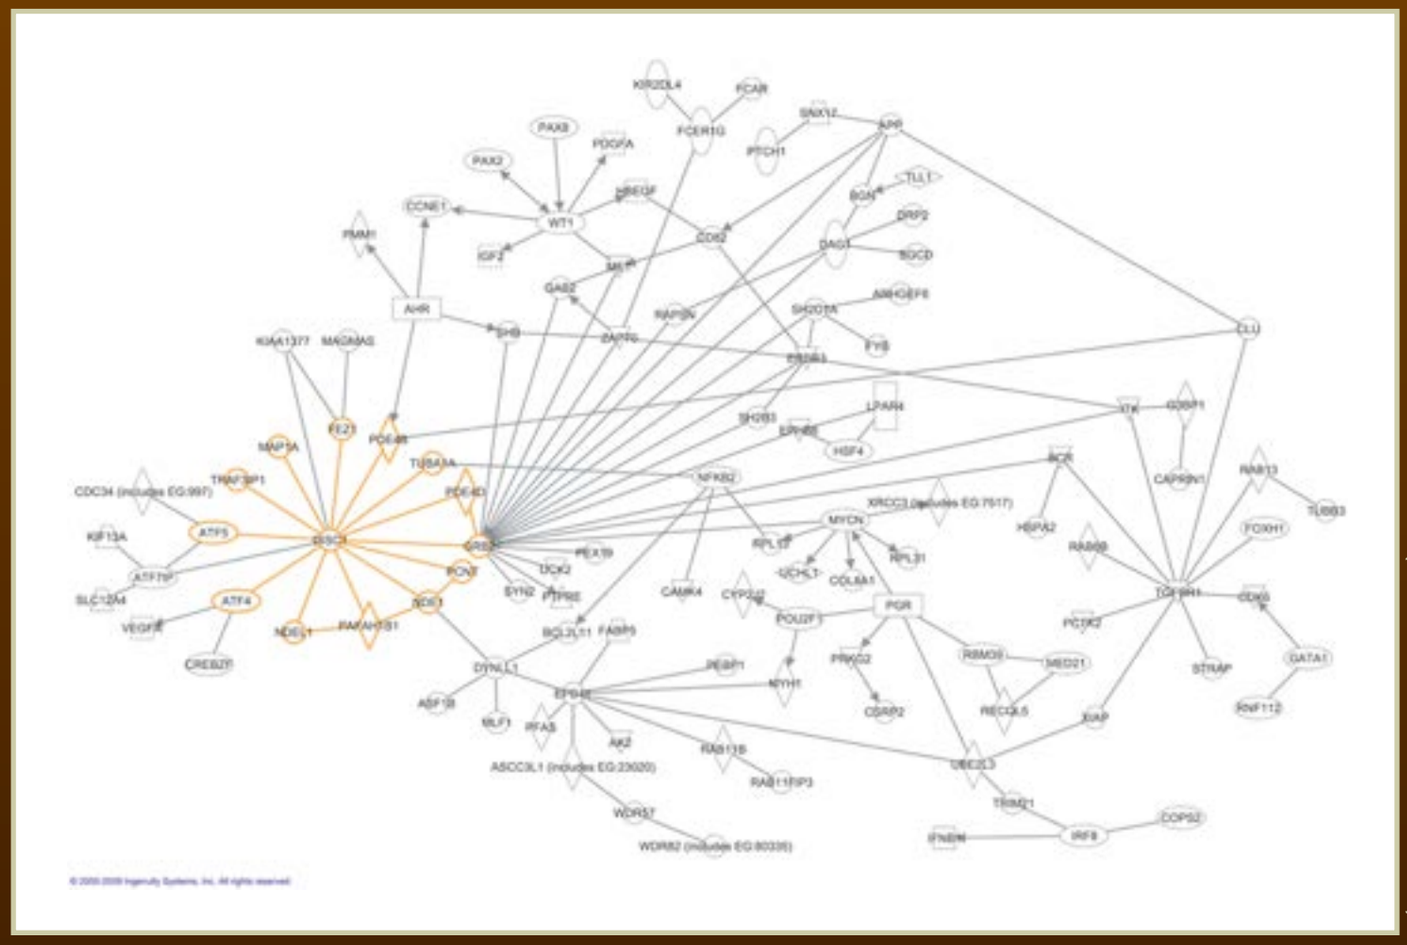
one gene — *produces* → *one trait*

gene var 1

gene var 2 ✗



In reality, genes produce traits through complex interactions:



We have very primitive theory for understanding these complex interaction networks

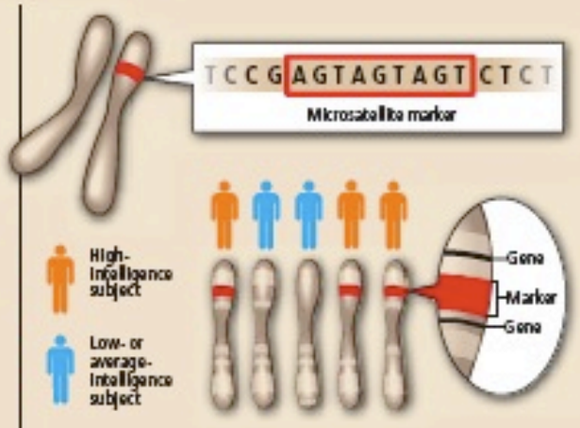
(*Source:* Porteous Hennah)

How will gene-screening technologies be used?

[TECHNIQUES]

HUNTING FOR GENES

Investigators have used various methods over the years to search for genes that might contribute to intelligence, which is a so-called quantitative trait—one present in all study subjects to greater or lesser degrees. Comparing the DNA of highly intelligent people with one another and with those of average or low intelligence can reveal patterns common to subjects of high intelligence. Those signatures, in turn, can flag the location of genes that influence intelligence levels, although such experiments have yet to conclusively identify any "intelligence genes."

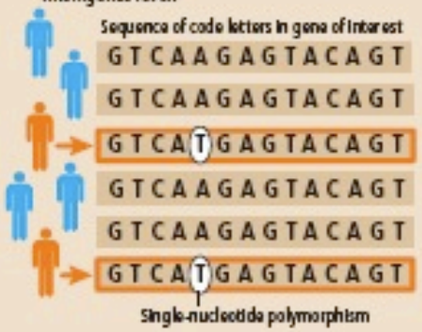


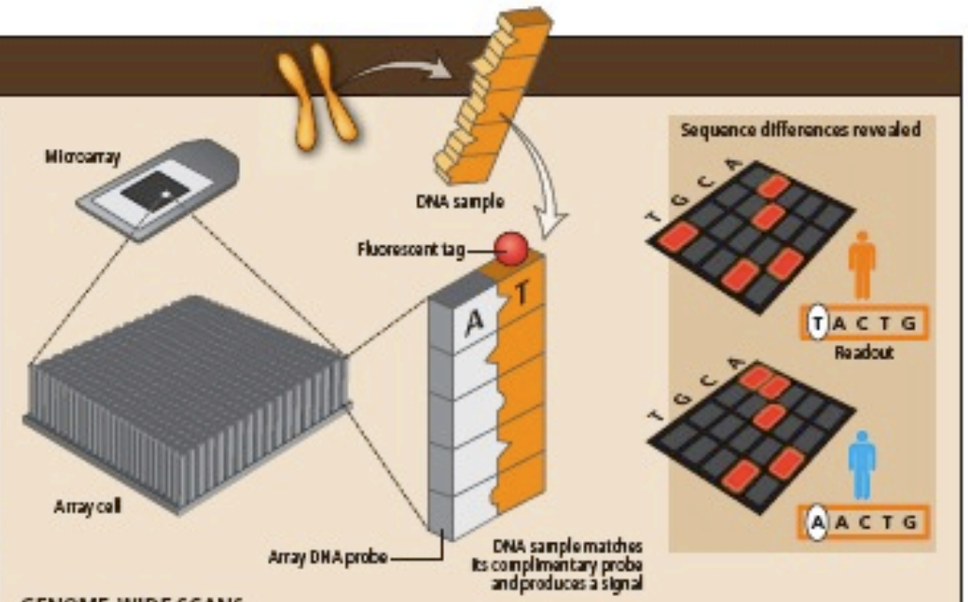
QUANTITATIVE TRAIT LOCI (QTL)

To find a chromosomal region, or "locus," implicated in a quantitative trait, scientists look first for repeated DNA sequences called microsatellite markers interspersed along the length of chromosomes. If particular markers appear more frequently in high-intelligence subjects, researchers will scan nearby DNA to identify neighboring genes.

CANDIDATE GENES

To find signs that a QTL gene or another gene already known to affect cognitive processes such as memory influences intelligence, scientists can compare the gene's DNA sequence in high- and low-intelligence subjects. If the same variations, called single-nucleotide polymorphisms (SNPs), appear more frequently in high-intelligence subjects, the pattern suggests the gene may contribute to intelligence level.





GENOME-WIDE SCANS

To identify new candidate genes, scientists can use microarrays to search the entire human genome for SNPs. Each cell of the array contains short DNA strands designed to pair with a particular sequence in a gene or gene-regulating region. When DNA samples are washed across the array, matches cause the cell to fluoresce (*red*). The single-nucleotide differences revealed in the DNA sequences of high-intelligence subjects and others can point to a gene, and a particular variant of it, that may contribute to intelligence.

http://www.jarvislab.net

- ★ 7,000 people screened for IQ and compared over 500,000 SNPs.
- ★ Only six SNPs showed any effect on IQ score.
- ★ The strongest contributions of any one of these SNPs was 0.4%; the combined effect of the six SNPs discovered was 1.2%.

Downloads

The following directories contain HapMap project related data, software, and documentation, that have been made publicly available. (See **HapMap Data Access Policy** for more information). More details about each dataset can be found in READMEs in the respective directories:

- **Bulk data**
  - **Genotypes**: Individual genotype data submitted to the DCC to date. **Phase 3** data is available in **PLINK format** and **HapMap format**.
  - **Frequencies**: Allele & genotype frequencies compiled from genotyping data submitted to the DCC to date. These have also been submitted to **dbSNP** and should be available in the next dbSNP build.
  - **LD Data**: Linkage disequilibrium properties D', LOD , R^2 compiled from the genotype data to date
  - **Phasing Data**: Phasing data generated using the PHASE software, compiled from the genotype data to date.
  - **Allocated SNPs**: dbSNP reference SNP clusters that have been picked and prioritized for genotyping according to several criteria (see info on **how SNPs were selected**). The file 00README contains per-chromosome SNP counts and further details.
  - **CNV Genotypes**: CNV data from HapMap3 samples.
  - **Recombination rates and Hotspots**: Recombination rates and hotspots compiled from the genotyping data.
  - **SNP assays**: Details about assays submitted to the DCC to date. PCR primers, extension probes etc., specific to each genotyping platform.
  - **Perlegen amplicons**: Details for mapping Perlegen amplicons to HapMap assayLSID. For primer sequences, see **Perlegen's** Long Range PCR Amplicon data.
  - **Raw data**: Raw signal intensity data from HapMap genotypes. Currently includes data from Affymetrix GeneChip 100k and 500k Mapping Arrays.
  - **Inferred genotypes**: Genotypes inferred using the method of Burdick et al. Nat Genet 38:1002-4.
  - **Mitochondrial and chrY haplogroups**: Classification of phase I HapMap samples into mtDNA and chrY haplogroups. The distribution shown in Table 4 of the HapMap phase I paper *(Nat Genet 38:1002-4)* corresponds to unrelated parents in each one of the populations analyzed.
